Written statement, short description of the project in English, no more than 250 words

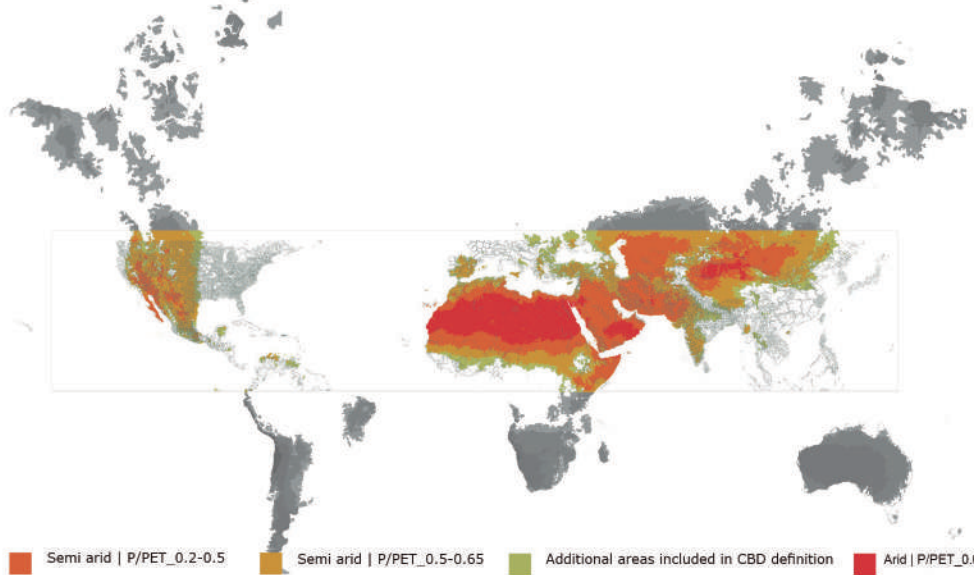

Along the 200 mm aridity line in Africa, conflict induced migration is the cause of environments degradation in this zone. Once registered as a refugee, one is displaced and resettled either internally or in a neighborhood country. Often, these host regions are already threatened by drought and have variable access to water and food. However, the arrival of refugees add pressures on fragile environments and trigger conflicts with host communities over the use of land and water resources. Due to the combined effect of continuous refugee influx and climate change, both population will soon live under insecurity due to continued land degradation and scarce resources including water and agriculture livelihood.

The thesis looks at underlying causes that lead to the humanitarian crisis as well as address immediate needs for food. It argues that settlement planning with low-technology irrigation strategies for herding and agriculture, seen in the context of the social structure, can ameliorate such conflicts. In the long run, a better living condition result in a more balanced relationship between local populations and refugees. The design part of the thesis The thesis explores the situation through the lens of the Kakuma camp, one of thee longest-lasting humanitarian settlements in Sub-Saharan Africa, as a test bed for the these technologies. It aims to create agriculture corridors as extensions of refugee settlements. With the adaptation of ancient arid climate and desert irrigation strategies, a minimal amount of water can be gathered for food harvesting as well as grazing.

FINDING DRY SEASON ARABLE AREAS OF KNOWN TECHNIQUES

The study begins with the examination of the water holding capacity of a given water harvesting techniques in the dry season is based on the understanding of shading performance. It is assumed that the types of techniques which are less shaded, are more likely to contain less water content than the ones that are well shaded due to higher evapotranspiration rate under the exposure of the sun. The Rhino grasshopper Sun path analysis provides the basic shade patterns over the course of the year is an effective tool to help understand which technique receives more shade than the other. As a result, we see that Zai pits receive most of the shades whilst trapezoidal bunds receive least shades among all the model techniques. The next step of the experiment attempts to simulate the hypothetical conditions on surface runoff over the model techniques with sand. Dropping sands directly on the models enable us to understand the catchment area of each model techniques. This experiment also takes into account wind resistance capability. In the second round of the experiment, sands were blown in face of the catchment area.

Define low points/ areas > Runoff flow directions and paths > Area with water content > Deployment of water harvesting interventions > Sites with development potentials > Catchment area > Distance to water resources > Land use planning

* Each cell represents an area of 200Mx200M²

DESIGN GUIDELINE

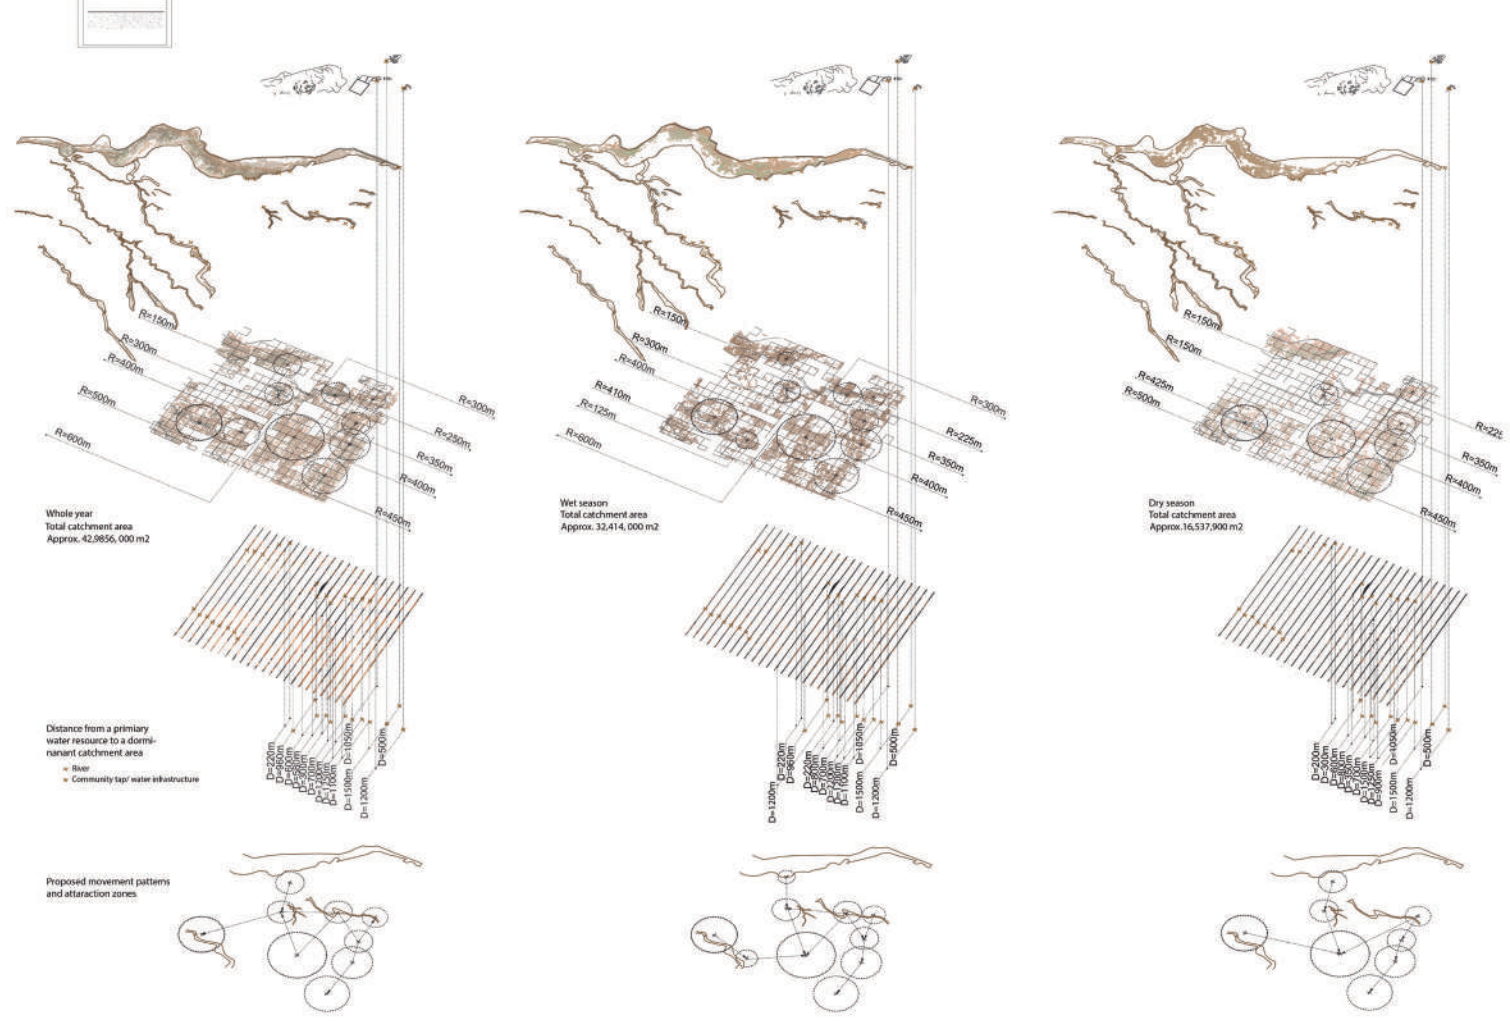

The set of drawings illustrate the seasonal changes of distance between the moisture zone and the nearest water resources. On site the water resources are comprised of a series of infrastructures wells, water towers and boreholes. Only in a few days (2-3 days), the dry rivers are filled up with water. The distance tend to be smaller in the wet season and big in the dry season.

 Dry river
 Refugee block

Serving as a constructive instrument, the drawing explores the soil moisture contents of study area in both dry and wet season through 23 section cuts. Each section is 200 meters apart. Spatially, where there the moisture presents in both seasons, it is possible to employ the water catchment techniques over the landscape. Landscape planning and land use design is heavy determined the by distances. Where the water catchment techniques are located, the landscape is suitable for agriculture actives.

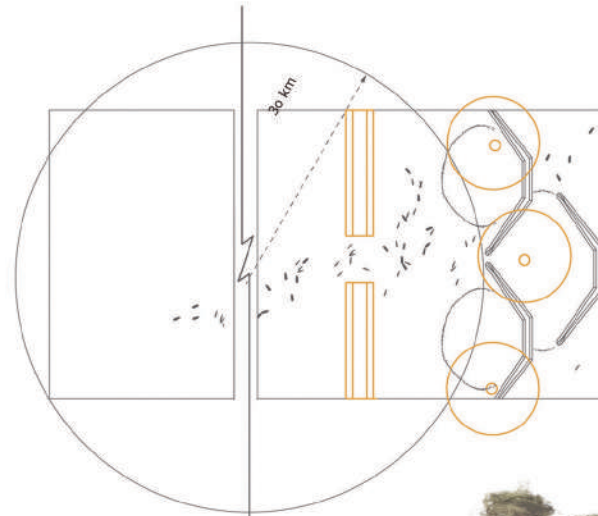

Zoning and land use

Area needs soil and water conservation
 Area reserved for livestock (goats, camels and cattle)
 Market
 Co-op
 Agriculture land reserved for host community
 Arable zone
 Wet season moisture
 Dry season moisture

WATER DELIVERY AND TERRITORY FORMATION

- + Adopted from Refugee camp planning standard, the maximum distance between any shelter and a water point will be 100 meters.
- + Community taps are encouraged to be placed at the in between camp zones while co-op space play a vital role in water delivery to the co-op area.

- + Where soil contains sufficient moisture, soil and water conservation techniques shall not be placed farther than 30kms away from the nomadic settlements
- + Trees with wide crowns provide sizable shaving area are encouraged to adapt near/adjacent to the interventions
- + To prevent animal ruination of soil, when necessary, wood fences are encouraged to be installed sound age large sized techniques such trapezoidal bunds
- + Earth bunds are necessary when land subject to wind erosion.

- + Where trees are not employable, shade structure is a good alternative for shading, ideally to be placed over the small scaled water harvesting techniques such as Zais
- + Fences are suitable structures for vines. Sweet photo vines are proved to be a good resources for goats
