<b>Department / Section / Program of belonging</b>	Landscape Architecture
<b>University / School</b>	KIT - Karlsruhe Institute of Technoloy

### Written statement, short description of the project in English, no more than 250 words

Urban challenges include traffic, Nature-Based Solutions, mixed land use, social integration, and healthy, equitable cities. GIS data aids in analyzing these complexities and presenting results graphically. The Trinational Eurodistrict Basel serves as an experimental site, examining cultural, natural, social, and built ecosystems for studying quality of life. Initially, quality of life indicators like Rhine access, parks, public transport, and meeting places were compared to population distribution. This determined favorable and unfavorable residential areas. The bicycle infrastructure in Basel was analyzed, comparing real user routes with the existing road network and proposed connections. Similarities and differences identified bicycle friendliness. Invasive Neophytes were studied to minimize their spread and integrate them into the local plant community. Threat levels and potential areas of spread were identified along the Rhine River and railroad tracks, along with causes of dispersal. The study on Tree Disservice mapped urban areas where severe allergies and respiratory problems are prevalent. Damage to trees within 100m of houses was assessed, categorizing areas from poor to poorly habitable. Tree diversity and nuisance for residents were also considered. Lastly, the relationship between tree age, environmental factors (e.g., nitrogen, ammonia), and urban influences (e.g., waste stations, land use) was explored. The attached maps illustrate the interconnected project stages, aiding the understanding of city development and the natural elements of quality of life.

Improving the quality of bike tracks-Improvolo

Factors influencing tree growth

Overview of the five narratives that were processed in four project stages divided into various subtopics. The summary map above shows one map from each of the project stages classify or analyze

# Tree disservices

Localize / Classify

Analyze

Therapize

For this project it was decided to map Trees. More specifically Tree disservice as described by Barcham in their tree selection guide.

The two disservices are mapped were allergy potential of trees aswell as their biogenic volatile organic compounds (BVOC) emissions, which are increased via temperature, air pollution and drought.

The main source of data was a combination of the tree cadastre of Basel and the species data from Barcham.

To accompany this, data from OSM and the Geodaten-shop from Basel for elements like streets, water, POIs were used.

GIS tools like Buffer, Clip, Extract, Merge, Count points in, and also Excel to manipulate the data were used. Using these tools, the main goal was to create a map of Basel which would shed light on urban Areas where life would be harder for people with intense allergies and respiratory problems.

This kind of mapping requires a lot of assumption and biases, so it cannot be described as scientifically accurate, but it still provides a different perspective on the matter.

It was decided to count the number of trees with different levels of disservices around every building in a 100m radius.

Using a first and simple excel formula (see Disservice Multiplier), buildings from bad to worse to live in in relation to totality of trees in the radius were mapped. The higher the value, the higher the overall disservice of trees in that range.

In a second formula (see Tree Nuisance Index) a narrowed it down a step more. The more the index approaches a value of 1, the more the totality of trees in a 100m Range around the building are of the highest disservice. This would then give Areas which present very little tree diversity and high nuisance for residents.

This method made it possible to create a more subtle map than in traditional urban analysis to understand the environment in a more precise and targeted way.
